To evaluate conformance of a particular implementation, it is necessary to have a statement of which capabilities and options have been implemented for a given standard. Such a statement is called a protocol implementation conformance statement (PICS).

### 1.1 Scope

This document provides the protocol implementation conformance statement (PICS) proforma for ZigBee specification ( 053474 r 17 ) in compliance with the relevant requirements, and in accordance

### 1.2 Purpose

The supplier of a protocol implementation claiming to conform to the ZigBee standard shall complete the following PICS proforma and accompany it with the information necessary to identify fully both the supplier and the implementation.

The protocol implementation conformance statement (PICS) of a protocol implementation is a statement of which capabilities and options of the protocol have been implemented. The statement is in the form of answers to a set of questions in the PICS proforma. The questions in a proforma consist of a systematic list of protocol capabilities and options as well as their implementation requirements. The implementation requirement indicates whether implementation of a capability is mandatory, optional, or conditional depending on options selected. When a protocol implementer answers questions in a PICS proforma, they would indicate whether an item is implemented or not, and provide explanations if an item is not implemented.

## 2 References

The following standards and specifications contain provisions, which through reference in this document constitute provisions of this specification. All the standards and specifications listed are normative references. At the time of publication, the editions indicated were valid. All standards and specifications are subject to revision, and parties to agreements based on this specification are encouraged to investigate the possibility of applying the most recent editions of the standards and specifications indicated below.

## Feature set

ZigBee coordinator

## ZigBee end device

ZigBee router

A collection of parameter values and configuration settings, collectively and loosely referred to as "knobs" in [R2], that determine the specific performance of a ZigBee stack variant and govern interoperability between stacks provided by different vendors.

An IEEE 802.15.4-2003 PAN coordinator operating in a ZigBee network.

An IEEE 802.15.4-2003 RFD or FFD participating in a ZigBee network, which is neither the ZigBee coordinator nor a ZigBee router.

An IEEE 802.15.4-2003 FFD participating in a ZigBee network, which is not the ZigBee coordinator but may act as an IEEE 802.15.4-2003 coordinator within its personal operating space, that is capable of routing messages between devices and supporting associations.

## 4 Acronyms and abbreviations

PICS Protocol Implementation Conformance Statement
RFD IEEE 802.15.4 Reduced Function Device

## 5 General description

The sections in this document are:

- Knob settings - details of values to be used for parameters specified in the ZigBee specification for tuning the operation of the ZigBee stack, including network, application and security settings.
- Functional description - further operational restrictions to be applied to all devices in this feature set where various approaches are otherwise supported by the ZigBee specification.
- Protocol implementation conformance statement (PICS) - a formal definition of functionality to be implemented in these devices.

These requirements aim to allow a designer to make necessary assumptions about what settings, features and safeguards will be in place in the networks in which a device will be deployed.

For clarity, settings applied to the ZigBee feature set will be marked with the string ZigBee and settings applied to the ZigBee-PRO feature set will be marked with the string ZigBee-PRO.

16 Knob settings

## 2 6.1 Introduction

3 This section specifies values for parameters specified in the ZigBee specification for tuning the 4 operation of the ZigBee and ZigBee-PRO stack. This section describes settings for both ZigBee and 5 ZigBee-PRO feature sets applied to the ZigBee-2007 Specification ([R1])

## $6 \quad 6.2$ Network settings

7 The network settings for the ZigBee and ZigBee-PRO feature sets are, for the most part, described in 8 the restricted PICS captured in Section 8.4. Those setting not covered by the PICS are listed in Table 2.

9
Table 2 - Network settings for this feature set

| Parameter Name | Setting |  | Comments |
| :---: | :---: | :---: | :---: |
| nwkTransactionPersistenceTime | 0x01f4 |  | Note that this value essentially "covers" the MAC attribute of the same name. <br> Note also that, while [R1] implies that this quantity has meaning only in beacon-enabled networks, it may actually be used in beaconless networks as well and, in that case, is a multiplier for aBaseSuperframeDuration. The value here yields a persistence time of 7.68 seconds using the 2.4 Ghz symbol rate from [R5] in a non-beaconed network. |
| nwkReportConstantCost | FALSE |  | The NWK layer in PRO shall always calculate routing cost on the basis of neighbor link cost and never report constant cost. |

## 10 6.3 Application settings

11 The application settings for the ZigBee and ZigBee-PRO feature sets are, for the most part, described 12 in the restricted PICS captured in Section 8.6. Those setting not covered by the PICS are listed in Table

14
Table 3 - Application settings for this feature set

| Parameter Name | Setting | Comments |  |  |
| :---: | :---: | :---: | :---: | :---: |
| Number of active endpoints per sleeping ZigBee end device (maximum) | - | \% | As the responsibility to arrange for caching of service discovery information lies with the end device itself, this parameter is not restricted. |  |
|  |  | 道 |  |  |
| Page 6 Copyright © 2008, The ZigBee Alliance. All rights reserved. <br> This is an unaccepted ZigBee specification draft, subject to change. <br> ZigBee-  <br> Alliance  |  |  |  |  |
|  |  |  |  |  |  |  |  |

2 The security settings for the ZigBee and ZigBee-PRO feature sets are listed in Table 4.
3 Table 4-Security settings for this feature set

| Parameter Na | ame | Setting |  | Comments |
| :---: | :---: | :---: | :---: | :---: |
| apsSecurityTimeoutPeriod | d | ```50ms * (2*NWK Maximum Depth) + (AES Encrypt/Decrypt times)``` |  | Where AES Encrypt/Decrypt times $=200 \mathrm{~ms}$, and <br> Where NWK Maximum Depth is assumed to be 5, meaning every device in the network can be reached in not more than 10 hops. <br> I.e. 700 milliseconds. Note that this timeout assumes worst case AES engine speeds and is not indicative of expected performance for most devices. |
|  |  |  |  | Where AES Encrypt/Decrypt times $=200 \mathrm{~ms}$, and <br> Where NWK Maximum Depth is assumed to be 15 , meaning every device in the network can be reached in not more than 30 hops. <br> I.e. 1.7 seconds. Note that this timeout assumes worst case AES engine speeds and is not indicative of expected performance for most devices. |

## Functional description

For the most part, the functioning of ZigBee and ZigBee-PRO with respect to the NWK layer, the APS layer and the ZDO is described in [R1]. However, the configuration details and operational requirements for devices operating under the ZigBee and ZigBee-PRO feature sets lead to some special functional considerations, which are detailed here.

### 7.1 Device roles

The basic roles performed by ZigBee devices in ZigBee and ZigBee-PRO networks are determined by their device type:

- The ZigBee coordinator initiates network formation, choosing the network channel, PAN ID and extended PAN ID in the process, and thereafter should act as a ZigBee router. It may also perform the roles of trust center and Network Channel Manager. With respect to binding, the ZigBee coordinator is expected to handle end device bind request on behalf of all end devices in the network but is not expected to be a global binding repository for the network.
- ZigBee routers are called upon to relay traffic on behalf of other devices in the network and, in particular, are required to act as routing agents on behalf of their end device children, which will typically not have the neighbor tables, routing tables, route discovery tables or broadcast transaction tables required to perform routing. Since end devices may sleep, ZigBee routers and ZigBee coordinators in their role of ZigBee routers may cache discovery information on behalf of their sleeping end-device children. A ZigBee router may perform the role of trust center and Network Channel Manager.
- ZigBee end devices are joined to and managed by ZigBee routers or the ZigBee coordinator. Because ZigBee-PRO networks are beaconless, there is no built-in synchronization mechanism between sleeping end devices and their router parents. End devices are free to set their own duty cycles within the broad polling limits defined by this feature set. End devices that wish to have their discovery information cached by their parent or some other device are responsible for using the discovery cache commands to achieve this.

Under the ZigBee and ZigBee-PRO feature sets, all devices are expected to manage their own binding tables if they use binding tables.

This section is valid for both the ZigBee and ZigBee-PRO feature sets.

### 7.2 ZigBee: Compatibility with Other Feature sets

Devices implementing the ZigBee feature set will advertise a feature set identifier of 1 in their beacon payloads as stated below in the additional restrictions for PICS item NLF4. In general, such devices will seek out and join networks in which the ZigBee coordinator and all ZigBee routers implement the ZigBee feature set and advertise this fact by placing a feature set identifier of 1 in their beacon payloads.

In order to provide compatibility with devices implemented according to the ZigBee-PRO feature set, ZigBee devices shall additionally be able to join networks which advertise a feature set identifier of 2 in their beacon payloads but the device must join the ZigBee-PRO networks as end devices and only those ZigBee-PRO networks employing standard network security.

This section is valid for the ZigBee feature set.

### 7.3 ZigBee-PRO: Compatibility with Other Feature sets

Devices implementing the ZigBee-PRO feature set will advertise a feature set identifier of 2 in their beacon payloads as stated below in the additional restrictions for PICS item NLF4. In general, such devices will seek out and join networks in which the ZigBee coordinator and all ZigBee routers implement the ZigBee-PRO feature set and advertise this fact by placing a feature set identifier of 2 in their beacon payloads.

In order to provide compatibility with devices implemented according to the ZigBee feature set, ZigBee-PRO devices shall additionally be able to join networks which advertise a feature set identifier of 1 in their beacon payloads but the device must join the ZigBee networks as end devices.

If a ZigBee PRO network is to allow ZigBee devices to join as end devices, it shall use the standard network security. If high security is used, ZigBee devices will not be able to be authenticated on the network.

This section is valid for the ZigBee-PRO feature set.

### 7.4 Binding tables

Binding tables, if used, shall be located on the source device. While binding is optional, devices that choose to use binding tables should allocate enough binding table entries to handle their own communications needs. This suggests that binding table size should be flexible enough that it can be set, at least at compile time, with some awareness of the actual intended usage of the device.

This section is valid for both the ZigBee and ZigBee-PRO feature sets.

### 7.5 Multicast mechanism and groups

Support for APS level multicasts is mandatory to support compatibility with ZigBee devices. The multicast groups are then established using the application level mechanisms. Support for routing of network level multicasts is mandatory in the ZigBee -Pro feature set.

ZigBee devices do not support network level multicasts.

### 7.6 Trust Center Policies and Security Settings

A ZigBee PRO network shall have a trust center uniquely pointed to by each device in the network through apsTrustCenterAddress within each network member device. It is beyond the scope of the PRO Feature set to describe how this value is set or whether it is changed and the Trust Center relocated to another device during operation. The only requirement of the PRO Feature set is that all devices in the network point to the one unique Trust Center and that the device pointed to as the Trust Center supplies the security services described by this document.

The trust center dictates the security parameters of the network, such as which network key type to use, settings of the service permissions table, when, if at all, to allow devices to use unsecured association to the network, and when, if at all, to allow an application master or link key to be set up between two devices. For interoperability, there are two distinct security settings that can be used within the ZigBee PRO feature set - a standard and a high security.

Networks can exist for periods without a trust center. There are some operations where it is necessary for the trust center to be operational in the network. These include initial network setup, key changes, and when joining and rejoining devices require updated keys.

A wide range of implementations are possible, depending on the requirements of the application. A high security trust center may allow the user to install devices "out-of-band", keep separate link keys for different devices, optionally ignore Mgmt_Permit Joining_req commands from other nodes, and configure application trust policies between devices or groups of devices, etc. A standard security trust center would not offer these advantages, but would not be required to carry the associated costs.

### 7.7 Battery powered devices

ZigBee-PRO networks may, of course, contain battery-powered devices. ZigBee routers are required to have their receivers enabled whenever they are not transmitting.

As mentioned above, ZigBee-PRO networks are beaconless networks and, in the absence of an explicit mechanism for synchronization and indirect transmission, sleeping devices must set their own duty cycles and use polling, under ZDO control, if they expect to receive frames that are directed to them when they are asleep. The feature set provides that parent devices, i.e. ZigBee routers and the ZigBee coordinator, hold frames for 7.5 seconds on behalf of sleeping end devices and this is also, roughly speaking, the maximum polling rate prescribed here. Devices may implement a polling interval longer than 7.5 seconds, however the application will then have to handle the potential loss of messages during longer sleep cycles.

### 7.8 Mains powered devices

It is assumed that for most ZigBee-PRO networks, the ZigBee coordinator and ZigBee routers will be mains-powered and always on in order to properly perform their required roles with respect to the operation of the network.

### 7.9 Persistent storage

The ZigBee-PRO feature set does not support devices without persistent storage. Devices have information required to be saved between unintentional restarts and power failures. See [R1] sections 2.2.8 and 3.6.8 for details of persistent data in the application and NWK layers. Various security material shall additionally be stored across power failures. All attributes in sections 4.3 .3 and 4.4.10 shall be stored, except that it is not mandatory to store those values which can safely be recovered using other stored information, or other methods.

### 7.10 Address Reuse

Re-use of previously assigned network short addresses in ZigBee-PRO devices is permitted subject to execution of the address conflict procedure by the device on the re-used address.

### 7.11 Duty cycle limitations and fragmentation

No mandatory restrictions are defined for intermittent, low channel usage data, although developers are encouraged to minimise bandwidth usage wherever possible.

Large acknowledged unicast transmissions should generally use the APS fragmentation mechanism, where supported, as this handles retransmissions, duplicate rejection, flow control and congestion control automatically. Use of the fragmentation mechanism is as specified in the application profile documents.

### 7.11.1 Vulnerability join

Vulnerability join shall be optional for networked devices, but support for it shall be mandatory for trust centers. The default for networks is permit joining is off. Permit joining is allowed for established time periods based on application requirements and specific instructions based on the system design.

Devices that join but do not successfully acquire and use the relevant security keys within the specified security timeout period shall disassociate themselves from the network, and their short address may be reused.

### 7.11.2 Pre-installation

Pre-installation is acceptable. Pre-installed devices are not exempt from the other requirements in this document. For example, a device certified as a trust center for this feature set shall support vulnerability installation of new devices, even if it is initially pre-installed.

### 7.12 Security

This feature set is designed to allow the efficient deployment of low cost devices, while also supporting the security requirements of highly sensitive applications. Installation and network maintenance procedures and administration are defined with the goal of satisfying the requirements of a range of applications within a single network infrastructure.

To achieve this, two security modes are specified: Standard mode and High Security mode. By default all applications will use the network key for communications. However, where confidentiality from other network nodes is required an application shall be permitted to use application link keys. Where link keys are required by specific application profiles, commands not secured with a link key shall be processed according to the rules established by the application profile.

The trust center plays a key role in determining the security settings in use in the network, and can optionally be implemented to apply further restrictions on the network. Please see section Error! Reference source not found. for details.

It is recommended that the trust center change the network key if it is discovered that any device has been stolen or otherwise compromised, and in order to avoid deadlock if all frame counter records become filled up. It is an application responsibility within the Trust Center to effect the change to the network key. There is no expectation that the network key be changed when adding a new device.

All devices may implement a service permissions table, which they may use to determine which devices are authorized to issue which commands. Unauthorized commands should not be carried out.

The trust center should be implemented to make appropriate choices about when to initiate an application master/link key shared between two devices. Where restrictions between devices are required it is the responsibility of the system installer/administrator to deploy a suitably intelligent trust center and configure it to make relevant checks before initiating sharing of application link keys between two devices. For example, it might facilitate policies based on certain times, certain manufacturers or device types, or when the trust center is configured in a certain way, etc. By default a simple trust center should always allow requests for link keys.

Devices may perform the relevant in or out of band authentication or key exchange before acquiring or using a link key with a new target.

### 7.12.1 Security Modes within PRO Networks

The feature set shall use two security modes: Standard mode and High Security mode.
With the Standard mode, network keys and application link keys are permitted for all devices. The network key type shall be the "standard" network key. It shall not be required that devices perform entity authentication with their parent on joining nor shall it be required to perform entity authentication between neighbors. If end devices wish to have a trust center link key, this should be requested using the request key command. Note that it is optional for the trust center to support link keys.

With the High Security mode, all three key types are permitted and shall be supported by all devices. The network key type shall be the "high security" network key. It shall be required that devices shall perform entity authentication with their parent on joining and it shall be required to perform entity authentication between neighbors. Frames from devices not in the neighbor table shall not be accepted.

When a "standard" type network key is in use, devices shall be permitted to update the network key when requested to do so by a command appropriately secured with the current network key. When a "high security" type of network key is in use this shall not be permitted. Additionally, in "high security", new trust center link keys may be deployed by SKKE only, ie: they shall not be sent using key transport.

Bit 6 of the capabilities field (security bit) shall be used to indicate whether or not a joining (or rejoining) device supports High Security mode. It shall be set to 0 if the joining or rejoining device does not support High Security mode (i.e. supports Standard mode), and shall be set to 1 if it does support High Security mode. The trust center may optionally make use of this information as part of its policy settings, for example when determining whether or not to allow the device onto the network, or when determining whether to initiate SKKE with a new joiner or send a link key and/or network key in the clear to the new deyice.

The above specifications are as currently described in the ZigBee specification.. Standard mode and High Security mode allow implementation of two different strengths of security depending on the application requirements and the specification supports a device indicating its security capabilities as it joins the network, thus giving the Trust Center the means to be able to accept or reject the device based on its policy.

# 8 Protocol implementation conformance statement (PICS) proforma 

### 8.1 Abbreviations and special symbols

| Notations for requirement status: |  |
| :--- | :--- |
| M | Mandatory |
| O | Optional |
| O.n | Optional, but support of at least one of the group of options labeled O.n is required. |
| $\mathrm{N} / \mathrm{A}$ | Not applicable |
| X | Prohibited |

### 8.2 ZigBee device types

| Item number | Item description | Reference | ZigBee Status | Feature set Support |  | Additional Constraints | Platform Support |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| FDT1 | Is this device capable of acting as a ZigBee coordinator? | [R1]/Preface (Definitions) |  |  | 0.1 |  | Yes |
|  |  |  |  |  | 0.1 |  | Yes |
| FDT2 | Is this device capable of acting as a ZigBee router? | [RI]/ <br> Preface (Definitions) |  |  | 0.1 |  | Yes |
|  |  |  |  |  | 0.1 |  | Pes |
| FDT3 | Is this a ZigBee end device? | [R1]/ <br> Preface (Definitions) |  | $\begin{aligned} & \mathbb{Z} \\ & \text { Mo } \\ & \text { N } \end{aligned}$ | 0.1 |  | Yes |
|  |  |  |  |  | 0.1 |  | Yes |

"item": Conditional, status dependent upon the support marked for the "item".
For example, if FDT1 and FDT2 are both marked "O.1" this indicates that the status is optional but at least one of the features described in FDT1 and FDT2 is required to be implemented, if this implementation is to follow the standard of which this PICS Proforma is a part.
